LM27313/-Q1 1.6-MHz Boost Converter With 30-V Internal FET Switch in SOT-23

1 Features

- LM27313-Q1 is an Automotive-Grade Product that is AEC-Q100 Grade 1 Qualified (−40°C to +125°C Operating Junction Temperature)
- 30-V DMOS FET Switch
- 1.6-MHz Switching Frequency
- Low $R_{DS(ON)}$ DMOS FET
- Switch Current up to 800 mA
- Wide Input Voltage Range (2.7 V to 14 V)
- Low Shutdown Current (< 1 µA)
- 5-Lead SOT-23 Package
- Uses Tiny Capacitors and Inductors
- Cycle-by-Cycle Current Limiting
- Internally Compensated

2 Applications

- White LED Current Source
- PDAs and Palm-Top Computers
- Digital Cameras
- Portable Phones, Games, and Media Players
- GPS Devices

3 Description

The LM27313/-Q1 switching regulator is a current-mode boost converter with a fixed operating frequency of 1.6 MHz.

The use of the SOT-23 package, made possible by the minimal losses of the 800-mA switch, and the small inductors and capacitors result in extremely high power density. The 30-V internal switch makes these solutions perfect for boosting to voltages of 5 V to 28 V.

This device has a logic-level shutdown pin that can be used to reduce quiescent current and extend battery life.

Protection is provided through cycle-by-cycle current limiting and thermal shutdown. Internal compensation simplifies design and reduces component count.

7 Detailed Description

7.1 Overview

The LM27313 is a switching converter IC that operates at a fixed frequency of 1.6 MHz using current-mode control for fast transient response over a wide input voltage range and incorporate pulse-by-pulse current limiting protection. Because this is current mode control, a 50-mΩ sense resistor in series with the switch FET is used to provide a voltage (which is proportional to the FET current) to both the input of the pulse width modulation (PWM) comparator and the current limit amplifier.

At the beginning of each cycle, the S-R latch turns on the FET. As the current through the FET increases, a voltage (proportional to this current) is summed with the ramp coming from the ramp generator and then fed into the input of the PWM comparator. When this voltage exceeds the voltage on the other input (coming from the Gm amplifier), the latch resets and turns the FET off. Because the signal coming from the Gm amplifier is derived from the feedback (which samples the voltage at the output), the action of the PWM comparator constantly sets the correct peak current through the FET to keep the output voltage in regulation.

Q1 and Q2 along with R3 - R6 form a bandgap voltage reference used by the IC to hold the output in regulation. The currents flowing through Q1 and Q2 will be equal, and the feedback loop will adjust the regulated output to maintain this. Because of this, the regulated output is always maintained at a voltage level equal to the voltage at the FB node “multiplied up” by the ratio of the output resistive divider.

The current limit comparator feeds directly into the flip-flop, that drives the switch FET. If the FET current reaches the limit threshold, the FET is turned off and the cycle terminated until the next clock pulse. The current limit input terminates the pulse regardless of the status of the output of the PWM comparator.

7.2 Functional Block Diagram

7.3 Feature Description

This device is designed as a current mode boost converter for a wide input voltage range. It features a very small package and operates at a high switching frequency. This allows for use of small passive components (inductors and capacitors), enabling small solution size. The device features also logic level shutdown, making it ideal for applications where low power consumption is desired. Control loop compensation is internal and no additional external components are required. Additional protection features are provided by deploying cycle-by-cycle current limiting and thermal shutdown.
7.4 Device Functional Modes

In normal operational mode, the device regulates output voltage to the value set with resistive divider. In addition, this device has a logic level shutdown pin (SHDN) that allows user to turn the device on/off by driving this pin high/low. Default setup is that this pin is connected to \( V_{IN} \) through pullup resistor (typically 50 k\( \Omega \)). When shutdown pin is low, the device is in shutdown mode consuming typically only 24 nA, making it ideal for applications where low power consumption is desirable.
8 Application and Implementation

NOTE
Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information
The device operates with input voltage in the range of 2.7 V to 14 V and provides regulated output voltage. This device is optimized for high-efficiency operation with minimum number of external components. Also, high switching frequency allows use of small surface mount components, enabling very small solution size. For component selection, refer to Detailed Design Procedure.

8.2 Typical Applications

8.2.1 Application Circuit $V_{IN}=5.0$ V, $V_{OUT}=12.0$ V, $I_{load}=250$ mA

![Typical Application Circuit](image1)

**Figure 12. Typical Application Circuit**

![Efficiency vs. Load Current](image2)

**Figure 13. Efficiency vs. Load Current**

8.2.1.1 Design Requirements
The device must be able to operate at any voltage within input voltage range.

Load Current must be defined in order to properly size the inductor, input and output capacitors. The inductor should be able to handle full expected load current as well as the peak current generated during load transients and start up. Inrush current at startup will depend on the output capacitor selection. More details are provided in Detailed Design Procedure.

Device has a shutdown pin (SHDN) that is used to enable and disable device. This pin is active low and should be tied to VIN if not used in application.
Typical Applications (continued)

8.2.1.2 Detailed Design Procedure

8.2.1.2.1 Selecting the External Capacitors

The LM27313 requires ceramic capacitors at the input and output to accommodate the peak switching currents the part needs to operate. Electrolytic capacitors have resonant frequencies which are below the switching frequency of the device, and therefore cannot provide the currents needed to operate. Electrolytics may be used in parallel with the ceramics for bulk charge storage which will improve transient response.

When selecting a ceramic capacitor, only X5R and X7R dielectric types should be used. Other types such as Z5U and Y5F have such severe loss of capacitance due to effects of temperature variation and applied voltage, they may provide as little as 20% of rated capacitance in many typical applications. Always consult capacitor manufacturer’s data curves before selecting a capacitor. High-quality ceramic capacitors can be obtained from Taiyo-Yuden, AVX, and Murata.

8.2.1.2.2 Selecting the Output Capacitor

A single ceramic capacitor of value 4.7 µF to 10 µF provides sufficient output capacitance for most applications. For output voltages below 10 V, a 10 µF capacitance is required. If larger amounts of capacitance are desired for improved line support and transient response, tantalum capacitors can be used in parallel with the ceramics. Aluminum electrolytics with ultra low ESR such as Sanyo Oscon can be used, but are usually prohibitively expensive. Typical AI electrolytic capacitors are not suitable for switching frequencies above 500 kHz due to significant ringing and temperature rise due to self-heating from ripple current. An output capacitor with excessive ESR can also reduce phase margin and cause instability.

8.2.1.2.3 Selecting the Input Capacitor

An input capacitor is required to serve as an energy reservoir for the current which must flow into the inductor each time the switch turns ON. This capacitor must have extremely low ESR and ESL, so ceramic must be used. We recommend a nominal value of 2.2 µF, but larger values can be used. Because this capacitor reduces the amount of voltage ripple seen at the input pin, it also reduces the amount of EMI passed back along that line to other circuitry.

8.2.1.2.4 Feed-Forward Compensation

Although internally compensated, the feed-forward capacitor Cf is required for stability (see Equation 1). Adding this capacitor puts a zero in the loop response of the converter. Without it, the regulator loop can oscillate. The recommended frequency for the zero fz should be approximately 8 kHz. Cf can be calculated using the formula:

\[
Cf = \frac{1}{(2 \times \pi \times R1 \times fz)}
\]

8.2.1.2.5 Selecting Diodes

The external diode used in the typical application should be a Schottky diode. If the switch voltage is less than 15V, a 20V diode such as the MBR0520 is recommended. If the switch voltage is between 15 V and 25 V, a 30-V diode such as the MBR0530 is recommended. If the switch voltage exceeds 25V, a 40V diode such as the MBR0540 should be used.

The MBR05xx series of diodes are designed to handle a maximum average current of 500 mA. For applications with load currents to 800 mA, a Microsemi UPS5817 can be used.

8.2.1.2.6 Setting the Output Voltage

The output voltage is set using the external resistors R1 and R2 (see Equation 2). A value of 13.3 kΩ is recommended for R2 to establish a divider current of approximately 92 µA. R1 is calculated using the formula:

\[
R1 = R2 \times \left( \frac{V_{OUT}}{V_{FB}} - 1 \right)
\]

8.2.1.2.7 Duty Cycle

The maximum duty cycle of the switching regulator determines the maximum boost ratio of output-to-input voltage that the converter can attain in continuous mode of operation. The duty cycle for a given boost application is defined as:
Typical Applications (continued)

Duty Cycle = \( \frac{V_{\text{OUT}} + V_{\text{DIODE}} - V_{\text{IN}}}{V_{\text{OUT}} + V_{\text{DIODE}} - V_{\text{SW}}} \)  

This applies for continuous mode operation.

The equation shown for calculating duty cycle incorporates terms for the FET switch voltage and diode forward voltage. The actual duty cycle measured in operation will also be affected slightly by other power losses in the circuit such as wire losses in the inductor, switching losses, and capacitor ripple current losses from self-heating. Therefore, the actual (effective) duty cycle measured may be slightly higher than calculated to compensate for these power losses. A good approximation for effective duty cycle is:

\[ \text{DC (eff)} = (1 - \text{Efficiency} \times \frac{V_{\text{IN}}}{V_{\text{OUT}}}) \]

where
- the efficiency can be approximated from the curves provided.

8.2.1.2.8 Inductance Value

The first question we are usually asked is: “How small can I make the inductor?” (because they are the largest sized component and usually the most costly). The answer is not simple and involves trade-offs in performance. More inductance means less inductor ripple current and less output voltage ripple (for a given size of output capacitor). More inductance also means more load power can be delivered because the energy stored during each switching cycle is:

\[ E = \frac{1}{2} L (i_p)^2 \]

where
- \( i_p \) is the peak inductor current.

An important point to observe is that the LM27313 will limit its switch current based on peak current. This means that because \( i_p(\text{max}) \) is fixed, increasing \( L \) will increase the maximum amount of power available to the load. Conversely, using too little inductance may limit the amount of load current which can be drawn from the output.

Best performance is usually obtained when the converter is operated in “continuous” mode at the load current range of interest, typically giving better load regulation and less output ripple. Continuous operation is defined as not allowing the inductor current to drop to zero during the cycle. It should be noted that all boost converters shift over to discontinuous operation as the output load is reduced far enough, but a larger inductor stays “continuous” over a wider load current range.

To better understand these tradeoffs, a typical application circuit (5V to 12V boost with a 10 µH inductor) will be analyzed.

Because the LM27313 typical switching frequency is 1.6 MHz, the typical period is equal to \( 1/f_{\text{SW(TYP)}} \), or approximately 0.625 µs.

We will assume: \( V_{\text{IN}} = 5 \text{ V}, V_{\text{OUT}} = 12 \text{ V}, V_{\text{DIODE}} = 0.5 \text{ V}, V_{\text{SW}} = 0.5 \text{ V} \). The duty cycle is:

\[ \text{Duty Cycle} = \frac{(12 \text{ V} + 0.5 \text{ V} - 5 \text{ V})}{(12 \text{ V} + 0.5 \text{ V} - 0.5 \text{ V})} = 62.5\% \]

The typical ON time of the switch is:

\[ (62.5\% \times 0.625 \mu\text{s}) = 0.390 \mu\text{s} \]

It should be noted that when the switch is ON, the voltage across the inductor is approximately 4.5 V.

Use the equation:

\[ V = L \frac{\text{di}}{\text{dt}} \]

Then, calculate the \( \frac{\text{di}}{\text{dt}} \) rate of the inductor which is found to be 0.45 A/µs during the ON time. Using these facts, we can then show what the inductor current will look like during operation:
Typical Applications (continued)

During the 0.390-µs ON time, the inductor current ramps up 0.176 A and ramps down an equal amount during the OFF time. This is defined as the inductor “ripple current”. It can also be seen that if the load current drops to about 33 mA, the inductor current will begin touching the zero axis which means it will be in discontinuous mode. A similar analysis can be performed on any boost converter, to make sure the ripple current is reasonable and continuous operation will be maintained at the typical load current values.

8.2.1.2.9 Maximum Switch Current

The maximum FET switch current available before the current limiter cuts in is dependent on duty cycle of the application. This is illustrated in Figure 15 which shows typical values of switch current as a function of effective (actual) duty cycle:

8.2.1.2.10 Calculating Load Current

As shown in Figure 14 which depicts inductor current, the load current is related to the average inductor current by the relation:

\[ I_{LOAD} = I_{IND(AVG)} \times (1 - DC) \]

where

- DC is the duty cycle of the application.  \hspace{1cm} (9)

The switch current can be found by:

\[ I_{SW} = I_{IND(AVG)} + \frac{1}{2} I_{RIPPLE} \]  \hspace{1cm} (10)

Inductor ripple current is dependent on inductance, duty cycle, input voltage and frequency:

\[ I_{RIPPLE} = DC \times (V_{IN} - V_{SW}) / (f_{SW} \times L) \]  \hspace{1cm} (11)
Typical Applications (continued)

Combining all terms, we can develop an expression which allows the maximum available load current to be calculated:

\[ I_{\text{LOAD}}(\text{max}) = \frac{(1 - DC) \times (I_{\text{SW}}(\text{max}) - DC \times (V_{\text{IN}} - V_{\text{SW}}))}{2fL} \]  

(12)

The equation shown to calculate maximum load current takes into account the losses in the inductor or turn-OFF switching losses of the FET and diode. For actual load current in typical applications, we took bench data for various input and output voltages and displayed the maximum load current available for a typical device in graph form:

![Figure 16. Max. Load Current vs V_IN](image)

8.2.1.2.11 Design Parameters \(V_{\text{SW}}\) and \(I_{\text{SW}}\)

The value of the FET ON voltage (referred to as \(V_{\text{SW}}\) in the equations) is dependent on load current. A good approximation can be obtained by multiplying the "ON Resistance" of the FET times the average inductor current.

FET ON resistance increases at \(V_{\text{IN}}\) values below 5V, because the internal N-FET has less gate voltage in this input voltage range (see Typical Characteristics). Above \(V_{\text{IN}} = 5\) V, the FET gate voltage is internally clamped to 5V.

The maximum peak switch current the device can deliver is dependent on duty cycle. The minimum switch current value (\(I_{\text{SW}}\)) is ensured to be at least 800 mA at duty cycles below 50%. For higher duty cycles, see Typical Characteristics.

8.2.1.2.12 Minimum Inductance

In some applications where the maximum load current is relatively small, it may be advantageous to use the smallest possible inductance value for cost and size savings. The converter will operate in discontinuous mode in such a case.

The minimum inductance should be selected such that the inductor (switch) current peak on each cycle does not reach the 800 mA current limit maximum. To understand how to do this, an example will be presented.

In this example, the LM27313 nominal switching frequency is 1.6 MHz, and the minimum switching frequency is 1.15 MHz. This means the maximum cycle period is the reciprocal of the minimum frequency:

\[ T_{\text{ON(max)}} = \frac{1}{1.15\text{MHz}} = 0.870 \mu\text{s} \]  

(13)

Assume: \(V_{\text{IN}} = 5\) V, \(V_{\text{OUT}} = 12\) V, \(V_{\text{SW}} = 0.2\) V, and \(V_{\text{DIODE}} = 0.3\) V. The duty cycle is:

\[ \text{Duty Cycle} = \frac{(12 \text{ V} + 0.3 \text{ V} - 5 \text{ V})}{(12 \text{ V} + 0.3 \text{ V} - 0.2 \text{ V})} = 60.3\% \]  

(14)

Therefore, the maximum switch ON time is:

\[ (60.3\% \times 0.870 \mu\text{s}) = 0.524 \mu\text{s} \]  

(15)
Typical Applications (continued)

An inductor should be selected with enough inductance to prevent the switch current from reaching 800 mA in the 0.524 µs ON time interval (see Figure 17):

\[
L = \frac{V \times (dt/dl)}{\text{mA}} \quad (16)
\]

\[
L = \frac{4.8 \text{ V} \times (0.524 \text{ µs} / 0.8 \text{ mA})}{1000} = 3.144 \text{ µH} \quad (17)
\]

In this case, a 3.3-µH inductor could be used, assuming it provided at least that much inductance up to the 800-mA current value. This same analysis can be used to find the minimum inductance for any boost application.

8.2.1.2.13 Inductor Suppliers

Some of the recommended suppliers of inductors for this product include, but are not limited to, Sumida, Coilcraft, Panasonic, TDK and Murata. When selecting an inductor, make certain that the continuous current rating is high enough to avoid saturation at peak currents. A suitable core type must be used to minimize core (switching) losses, and wire power losses must be considered when selecting the current rating.

8.2.1.2.14 Shutdown Pin Operation

The device is turned off by pulling the shutdown pin low. If this function is not going to be used, the pin should be tied directly to \( V_{IN} \). If the SHDN function will be needed, a pullup resistor must be used to \( V_{IN} \) (50 kΩ to 100 kΩ is recommended), or the pin must be actively driven high and low. The SHDN pin must not be left unterminated.

8.2.1.3 Application Curves

![Figure 18. Typical Startup Waveform for Vin = 3.3 V, Vout = 12 V](image)

![Figure 19. Typical Startup Waveform for Vin = 5.0 V, Vout = 12 V](image)
Typical Applications (continued)

8.2.2 Application Circuit $V_{\text{IN}}=5.0\text{V}$, $V_{\text{OUT}}=20.0\text{V}$, $I_{\text{load}}=150\text{mA}$

8.2.2.2 Detailed Design Procedure

See Detailed Design Procedure.

8.2.2.3 Application Curves

See Application Curves.
9 Power Supply Recommendations

The LM27313 is designed to operate from an input voltage supply range from 2.7 V to 14 V. This input supply should be able to withstand the maximum input current and maintain a voltage above 2.7 V. In cases where input supply is located farther away (more than a few inches) from LM27313, additional bulk capacitance may be required in addition to the ceramic bypass capacitors.

10 Layout

10.1 Layout Guidelines

High-frequency switching regulators require very careful layout of components in order to get stable operation and low noise. All components must be as close as possible to the LM27313 device. It is recommended that a 4-layer PCB be used so that internal ground planes are available.

Some additional guidelines to be observed:
1. Keep the path between L1, D1, and C2 extremely short. Parasitic trace inductance in series with D1 and C2 will increase noise and ringing.
2. The feedback components R1, R2 and CF must be kept close to the FB pin of the LM27313 to prevent noise injection on the high impedance FB pin.
3. If internal ground planes are available (recommended) use vias to connect directly to the LM27313 ground at device pin 2, as well as the negative sides of capacitors C1 and C2.

10.2 Layout Example

![Figure 22. Recommended PCB Component Layout](image)

10.3 Thermal Considerations

At higher duty cycles, the increased ON time of the FET means the maximum output current will be determined by power dissipation within the LM27313 FET switch. The switch power dissipation from ON-state conduction is calculated by:

\[ P_{SW} = DC \times I_{IND(AVG)}^2 \times R_{DS(ON)} \] (18)

There will be some switching losses as well, so some derating needs to be applied when calculating IC power dissipation.
11 Device and Documentation Support

11.1 Device Support

11.1.1 Third-Party Products Disclaimer
TI’S PUBLICATION OF INFORMATION REGARDING THIRD-PARTY PRODUCTS OR SERVICES DOES NOT CONSTITUTE AN ENDORSEMENT REGARDING THE SUITABILITY OF SUCH PRODUCTS OR SERVICES OR A WARRANTY, REPRESENTATION OR ENDORSEMENT OF SUCH PRODUCTS OR SERVICES, EITHER ALONE OR IN COMBINATION WITH ANY TI PRODUCT OR SERVICE.

11.2 Related Links
The table below lists quick access links. Categories include technical documents, support and community resources, tools and software, and quick access to sample or buy.

(1) The marketing status values are defined as follows:
- **ACTIVE**: Product device recommended for new designs.
- **LIFEBUY**: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
- **NRND**: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
- **PREVIEW**: Device has been announced but is not in production. Samples may or may not be available.
- **OBSOLETE**: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check [http://www.ti.com/productcontent](http://www.ti.com/productcontent) for the latest availability information and additional product content details.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a “~” will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

NOTES:
A. All linear dimensions are in millimeters.
B. This drawing is subject to change without notice.
C. Body dimensions do not include mold flash or protrusion. Mold flash and protrusion shall not exceed 0.15 per side.
D. Falls within JEDEC MO-178 Variation AA.
NOTES:
A. All linear dimensions are in millimeters.
B. This drawing is subject to change without notice.
C. Customers should place a note on the circuit board fabrication drawing not to alter the center solder mask defined pad.
D. Publication IPC-7351 is recommended for alternate designs.
E. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Example stencil design based on a 50% volumetric metal load solder paste. Refer to IPC-7525 for other stencil recommendations.
IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as “components”) are sold subject to TI’s terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI’s terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers’ products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers’ products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI’s goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or “enhanced plastic” are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have not been so designated is solely at the Buyer’s risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
